ABSTRACT

The growing incorporation of digital devices into the daily lives of young children has heightened academic discourse around the significance of digital play in early childhood education. Although play-based learning is fundamental to preschool curricula, interactive educational technology is progressively being used to enhance early learning experiences. Nonetheless, empirical evidence on the simultaneous effects of digital play on cognitive and socioemotional development in preschoolers is scarce, particularly in curriculum-aligned classroom settings. This study investigated the effects of structured digital play with interactive educational tools on the development of preschool children. The study employed a quasi-experimental mixed-methods design, involving 72 children aged 4 to 6 years from urban preschools, randomly assigned to experimental and control groups. The results indicated that children in the experimental group showed markedly greater improvements in attention, executive functioning, early literacy and numeracy, and problem-solving skills than those in the control group (Cohen's d = 0.54–0.68). Moreover, notable improvements were observed in emotional regulation, social interaction, cooperation, and empathy (Cohen's d = 0.63–0.70). Classroom observations indicated elevated engagement, collaborative behavior, positive emotional expressions, and the essential role of teacher mediation during digital play. The findings indicate that purposefully designed and integrated digital play can serve as a comprehensive pedagogical strategy in early childhood education. The research provides significant insights into early childhood curriculum development, digital teaching methods, and educators' professional growth in technology-integrated learning environments.

Keywords: Digital Play; Early Childhood Education; Cognitive Development; Socio-Emotional Development; Curriculum Integration.

1. INTRODUCTION

The swift digitalization of daily life has significantly altered the ways in which young children engage with their surroundings, obtain knowledge, and formulate social meanings (Colvert et al., 2024; Nash, 2025; Xiao et al., 2024). In modern countries, preschool-aged children are increasingly exposed to digital gadgets, including tablets, smartphones, and interactive learning platforms, frequently prior to commencing formal education. This first exposure has sparked

increased academic interest in examining how digital play characterized as play activities facilitated by digital technologies affects early learning processes. In early childhood education (ECE), play is acknowledged as a fundamental pedagogical method that facilitates comprehensive development, including cognitive, linguistic, social, and emotional growth (Chen & Ding, 2024; Guo et al., 2022; Misirli et al., 2025; Yelizarova et al., 2025). As digital technologies integrate into children's play experiences, inquiries emerge concerning their alignment with recognized developmental principles and curricular objectives in early learning environments.

From a developmental standpoint, early infancy is a pivotal phase characterized by swift brain development, increased neuroplasticity, and the establishment of fundamental cognitive and socio-emotional skills. Cognitive development in preschool years includes essential skills including attention regulation, memory, problem-solving, early numeracy, and emerging reading. Concurrently, socio-emotional development encompasses the attainment of self-regulation, empathy, cooperation, emotional expression, and peer interaction (Ho & King, 2021; Margolis & Gabard-Durnam, 2025; Marzola et al., 2023; Peña, 2026). Conventional play-based learning environments defined by symbolic play, tactile engagement with objects, and social interaction have demonstrated efficacy in cultivating these competencies. The incorporation of interactive educational technologies presents new forms of engagement that can either improve or limit developmental outcomes, contingent upon the design, mediation, and contextualization of digital play within early childhood curricula (Bourbour, 2023; Hu et al., 2021; Yang et al., 2022).

In recent years, interactive educational technologies have progressed from passive screen-based information to more responsive, adaptable, and immersive digital experiences. Educational applications, touchscreen games, and interactive storytelling platforms increasingly integrate features such as instantaneous feedback, multimodal representations, adaptive difficulty levels, and simulated social interactions. Advocates contend that these attributes can facilitate learning, maintain focus, and customize educational experiences for young students (Bahroun et al., 2023; Mhlongo et al., 2023; Partarakis & Zabulis, 2024). From this viewpoint, digital play can enhance traditional play by providing innovative problem-solving opportunities, aiding conceptual comprehension, and cultivating motivation through gamified aspects. As a result, digital play is increasingly regarded as a genuine element of early learning environments rather than a marginal or solely recreational activity.

Notwithstanding these optimistic assertions, apprehensions remain about the developmental suitability of digital play in early life. Critics emphasize the dangers linked to prolonged screen time, diminished physical activity, restricted in-person social connection, and possible overstimulation (Crescenzi-Lanna, 2022; Istenič et al., 2023; Johannes et al., 2022). From a socio-emotional perspective, there is concern that digitally mediated play may reduce opportunities for genuine peer connection, emotional bargaining, and collaborative problem-solving elements that are fundamental to social learning in early infancy. The cognitive advantages of digital play are frequently presumed rather than substantiated via empirical evidence, especially when educational technologies are employed without pedagogical direction or connection with curricular goals (Loudoun et al., 2024; Murcia et al., 2024; Setty, 2024). These discussions highlight the necessity for detailed, evidence-driven analyses of the impact of interactive educational technology on the cognitive and socio-emotional development of preschool-aged children.

Current empirical research on digital play and early learning has yielded inconclusive results. Research indicates that effectively designed interactive applications can enhance early literacy, numeracy, and executive functioning by engaging children in goal-oriented tasks and provide

prompt feedback (Harmon & Arnold, 2024; Hoareau & Tazouti, 2024; Kara & Cagiltay, 2024; Pellas, 2025). Conversely, other research indicate negligible or inconsistent impacts, especially when digital activities are not incorporated into comprehensive learning frameworks or are utilized in isolation. Moreover, the existing literature predominantly emphasizes cognitive outcomes, typically assessed via short-term achievement improvements, but socio-emotional aspects are afforded relatively little systematic consideration (Arbués et al., 2025; Ferreira et al., 2024; Nanda et al., 2025). Socio-emotional factors are often regarded as secondary results rather than essential elements of early learning and development.

A significant shortcoming of previous studies is its inclination to regard digital play as a uniform concept. Numerous studies do not distinguish among various forms of digital play, degrees of interactivity, or the influence of adult mediation on children's learning experiences. Interactive educational technologies exhibit significant diversity in their pedagogical frameworks, encompassing drill-based applications and open-ended exploration environments that foster creativity and collaboration (Gkrimpizi et al., 2023; Lorenz-Spreen et al., 2022; Wang et al., 2022). Failing to distinguish among these types impedes the derivation of meaningful findings regarding the developmental effects of digital activity. Moreover, a significant portion of the current research originates from controlled laboratory environments or brief interventions, which may fail to fully represent the intricate, contextual dynamics of learning in actual preschool settings.

A significant gap pertains to the incorporation of digital play into early childhood courses. Although curriculum frameworks increasingly recognize the significance of digital literacy and technology-enhanced learning, empirical studies seldom investigate the integration of interactive technologies within play-based curricular practices (Li et al., 2024; Pyle et al., 2023). Consequently, there is a restricted comprehension of the interplay between digital play and recognized educational principles, including child-centered learning, scaffolding, and social engagement. This disparity is especially pronounced concerning socio-emotional development, which is significantly shaped by classroom dynamics, teacher facilitation, and peer interactions. Evaluations of digital play, devoid of a curriculum-oriented perspective, may overlook the contextual factors that shape its educational significance.

Furthermore, little research employs a comprehensive approach that concurrently investigates cognitive and socio-emotional consequences of digital play. The inclination to segregate these domains fails to acknowledge the interconnectedness of cognitive and emotional processes in early childhood development (Lehrl et al., 2021; Saleme et al., 2021). Engagement in problem-solving tasks is frequently influenced by motivation, emotional management, and social connection. Comprehending the influence of interactive educational technology necessitates analytical frameworks that consider these interdependencies instead of regarding cognitive and socio-emotional development as separate entities.

This study addresses existing limitations by fulfilling the necessity for empirically based, contextually relevant research on digital play in early childhood education. This study aims to assess the impact of interactive educational technology on cognitive and socio-emotional development when included into preschool learning contexts. The study emphasizes preschoolers, a developmental phase where play-based learning is essential and developmental pathways are notably flexible. This research positions interactive technology into daily classroom practices, highlighting its function as a pedagogical tools that engage with social, emotional, and cognitive processes, rather than viewing digital play as a solitary activity.

This study demonstrates that digital play, when purposefully created and integrated into play-based curricula, can significantly enhance early learning results. This study systematically

evaluates children's cognitive and socioemotional development and demonstrates that interactive educational technology can enhance core skills, including attention, problem-solving, emotion regulation, and peer interaction. The findings underscore the significance of adult mediation and curricular congruence in optimizing the developmental advantages of digital play. This study enhances the comprehension of digital play in early childhood education by presenting empirical evidence that connects cognitive and socio-emotional domains, offering essential insights for curriculum designers, educators, and policymakers aiming to incorporate technology in developmentally suitable manners.

2. METHOD

2.1 Research Design

This research utilized a quasi-experimental design with an integrated mixed-methods approach to investigate the effects of digital play on the cognitive and socio-emotional development of preschoolers. This design was chosen to facilitate systematic comparison between children engaged in technology-enhanced digital play activities and those involved in traditional play-based learning, while addressing the ethical and practical limitations of early childhood educational environments. The mixed-methods approach facilitated the amalgamation of quantitative developmental metrics with qualitative observer data, yielding a more holistic comprehension of children's learning experiences. The intervention involved organized digital play sessions employing interactive educational tools aimed at enhancing problem-solving, attentiveness, and social engagement. The study spanned eight weeks and included three phases: a pre-intervention evaluation, an implementation period featuring consistent digital play activities, and a post-intervention evaluation. This incremental strategy guaranteed the methodical assessment of developmental alterations resulting from the intervention.

2.2 Research Setting and Participants

The research was performed in four preschools situated in an urban environment, encompassing both public and private early childhood education establishments. Participants consisted of children aged 4 to 6 years (N = 72), allocated to an experimental group (n = 36) and a control group (n = 36) according to pre-existing classroom configurations. The inclusion criteria mandated that children be ordinarily developing and consistently enrolled in the participating preschools, whereas those with recognized developmental abnormalities were excluded. The intervention included eight educators, each tasked with conducting daily instructional activities. A cluster sampling method was utilized to choose intact classrooms, so ensuring ecological validity and reducing disruption to standard educational routines, as shown in Table 1.

Table 1. Demographic Profile of Research Setting and Participants

Group	Number of Children	Average Age (Years)	Male (%)	Female (%)	Public Preschool (%)	Private Preschool (%)
Experimental	36	5.1	53	47	56	44
Control	36	5.0	50	50	58	42

Table 1 provides a detailed demographic description of the research participants and educational environments. Seventy-two preschool children aged 4 to 6 years were equitably allocated between experimental and control groups, facilitating a balanced comparison. The mean

age among groups was similar, reducing developmental bias. The gender proportion was reasonably equitable, mirroring standard classroom compositions in early childhood education. The inclusion of both public and private preschools underscores the ecological diversity of the sample, hence augmenting the generalizability of the findings. This comprehensive demographic mapping enhances methodological rigor by showing that the observed developmental consequences are not due to demographic imbalance, as shown in Figure 1.

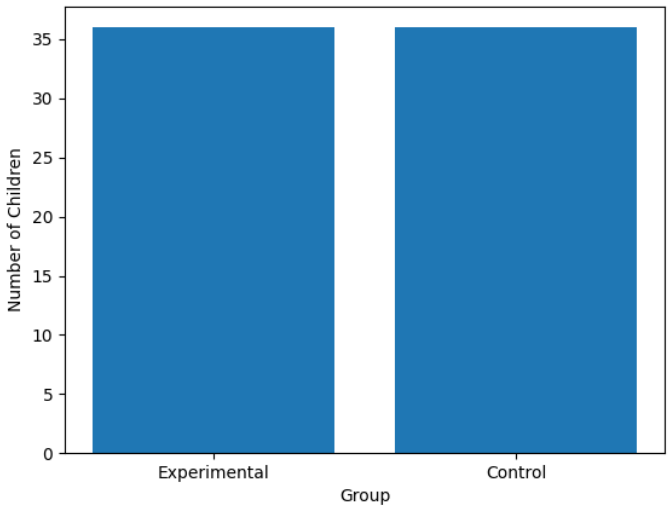

Figure 1. Distribution of Participants by Research Group

Figure 1 depicts the equitable allocation of participants between the experimental and control groups. Each group comprised 36 youngsters, representing a calculated methodological choice to maintain uniformity in sample size. This balance is essential in quasi-experimental research, since it improves statistical comparability and mitigates the danger of sample bias. Uniform group sizes facilitate a more rigorous assessment of intervention effects associated with digital play activities. This picture visually confirms participant parity, so enhancing the internal validity of the study design and offering empirical support for subsequent comparative assessments of cognitive and socio-emotional development outcomes.

2.3 Digital Play Intervention

The digital play intervention employed interactive educational programs, game-based learning platforms, and digital narrative tools tailored for early childhood learners. These technologies were built on play-based learning, constructivist pedagogy, and developmental appropriateness, highlighting exploration, feedback, and social engagement. Digital play sessions were held thrice weekly, with each session enduring 30 minutes during the intervention period. Activities were designed to incorporate both independent inquiry and small-group collaborative play to enhance cognitive engagement and peer interaction. Educators assumed a proactive mediating role by structuring tasks, facilitating reflection, and promoting social interaction. All digital play activities were meticulously integrated with the preschool curriculum to enhance specific cognitive and socio-emotional development objectives.

2.4 Instruments and Measures

Cognitive development was evaluated utilizing a series of age-appropriate standardized tools that test attention and executive functioning, early reading and numeracy, and problem-solving skills. Tasks comprised organized attention-switching exercises, preliminary symbol identification and counting activities, as well as game-oriented problem-solving evaluations integrated into play scenarios. These tools exhibited satisfactory content validity and reliability, with internal consistency coefficients surpassing the suggested thresholds for early childhood assessment. Socio-emotional development was evaluated using teacher and observer report scales that assessed emotional control, social interaction, collaboration, empathy, and peer connections. The tests were modified for preschool environments and demonstrated acceptable psychometric characteristics, encompassing concept validity and inter-item reliability. Classroom observations were executed during digital play sessions utilizing a controlled observation protocol. A rubric for observation, featuring explicitly specified behavioral indications, facilitated data collecting. Inter-rater reliability was determined via separate coding conducted by trained observers and the computation of agreement coefficients before analysis.

2.5 Data Collection Procedures

The data collection occurred in three consecutive phases. Initially, pre-test evaluations were conducted to assess children's baseline cognitive and socio-emotional development before the intervention. The implementation phase entailed the methodical incorporation of digital play activities into standard classroom routines, accompanied by continuous classroom observations to record children's involvement and interactions. Subsequent to the intervention, post-test evaluations were performed utilizing identical instruments to determine developmental alterations. Qualitative data were gathered using structured classroom observations and concise teacher reflection journals to obtain contextual perspectives. Ethical protocols encompassed acquiring informed consent from parents or guardians, securing kid assent, and upholding confidentiality and anonymity during the data gathering process.

2.6 Data Analysis

Quantitative data were evaluated for completeness, normalcy, and outliers before analysis. Descriptive statistics were computed to include individuals' cognitive and socio-emotional scores. Inferential methods, such as paired-sample t-tests and ANCOVA, were utilized to assess differences between pre-test and post-test variables while controlling for baseline variations. Effect sizes were computed to ascertain the magnitude of intervention effects. Qualitative data from classroom observations and teacher reflections were subjected to theme analysis, which entailed systematic coding and the construction of categories. Trustworthiness was established via data triangulation and peer debriefing. Quantitative and qualitative findings were synthesized during interpretation to yield a thorough knowledge of the influence of digital play on early learning.

2.7 Ethical Considerations

Ethical approval for the study was secured from the appropriate institutional review board before data collection commenced. Informed consent was obtained from parents or legal guardians following the provision of comprehensive information regarding the study's aims, methodologies, and any dangers. Furthermore, child assent was secured through age-appropriate explanations, guaranteeing that children's participation was voluntary and considerate of their

comfort. All data were managed with stringent confidentiality, and participants' identities were anonymised through coded identifiers. Access to research data was restricted to the research team, and all procedures complied with ethical requirements for studies involving young children.

3. RESULTS AND DISCUSSION

3.1 Results

a. Preliminary Data Analysis

Initial studies were performed to investigate the distributional characteristics of the data and to determine baseline equivalence between the experimental and control groups. Descriptive statistics revealed that, at the pre-test phase, mean scores for cognitive development (attention, early literacy and numeracy, and problem-solving) and socio-emotional development (emotional control, social interaction, and empathy) were similar across groups. The post-test descriptive data indicated elevated mean scores for the experimental group on both cognitive and socio-emotional assessments, implying favorable trends subsequent to the digital play intervention.

Assumption testing was conducted prior to inferential analysis. Normality tests, encompassing skewness and kurtosis indices alongside the Shapiro–Wilk test, demonstrated that the data followed a normal distribution. Levene's test validated the homogeneity of variance, revealing no substantial violations. The results corroborated the appropriateness of parametric statistical studies. The baseline equality of the experimental and control groups was further assessed by independent-sample t-tests on pre-test scores. No statistically significant differences were identified, suggesting that the two groups were comparable prior to the intervention. The established baseline comparability enhanced the internal validity of future studies investigating the impact of digital play on developmental outcomes.

b. Effects of Digital Play on Cognitive Development

The findings demonstrated statistically significant enhancements in cognitive development in youngsters within the experimental group after the digital play intervention. Metrics of attention and executive functioning shown significant improvements, as post-test scores were markedly elevated compared to pre-test scores ($p < .05$), signifying better concentration and cognitive adaptability. Likewise, early reading and numeracy skills exhibited substantial enhancement in the experimental group relative to the control group, as indicated by elevated mean differences and moderate effect sizes (Cohen's $d = 0.45–0.62$). Children exposed to interactive instructional technologies shown significant enhancements in problem-solving skills, especially in tasks necessitating logical reasoning and goal-oriented thinking. The control group had only minimal improvements in cognitive assessments. The quantitative data indicate that structured digital play positively and significantly influences preschoolers' cognitive development. The amalgamation of statistically significant outcomes and moderate effect sizes highlights the efficacy of interactive digital play as a cognitively enriching element in early childhood educational settings, as shown in Table 2.

Table 2. Pre- and Post-Test Cognitive Development Scores and Effect Sizes

Cognitive Domain	Experimental (Pre)	Experimental (Post)	Control (Pre)	Control (Post)	Effect Size (Cohen's d)
Attention & Executive Function	62.4	75.6	61.9	64.2	0.68
Early Literacy & Numeracy	60.8	73.1	60.5	63.0	0.54
Problem-Solving	61.2	74.4	60.9	63.5	0.61

Table 2 displays comprehensive pre- and post-test cognitive growth scores across three domains. The experimental group of children shown significant improvements in attention, executive functioning, early reading, numeracy, and problem-solving skills after the digital play intervention. The control group shown only slight enhancements in all areas. The computed effect sizes varied from moderate to large (Cohen's d = 0.54–0.68), signifying substantial intervention effects beyond mere statistical significance. The findings indicate that organized and interactive digital play can significantly improve several aspects of cognitive development in toddlers when incorporated into educational practices, as shown in Figure 2.

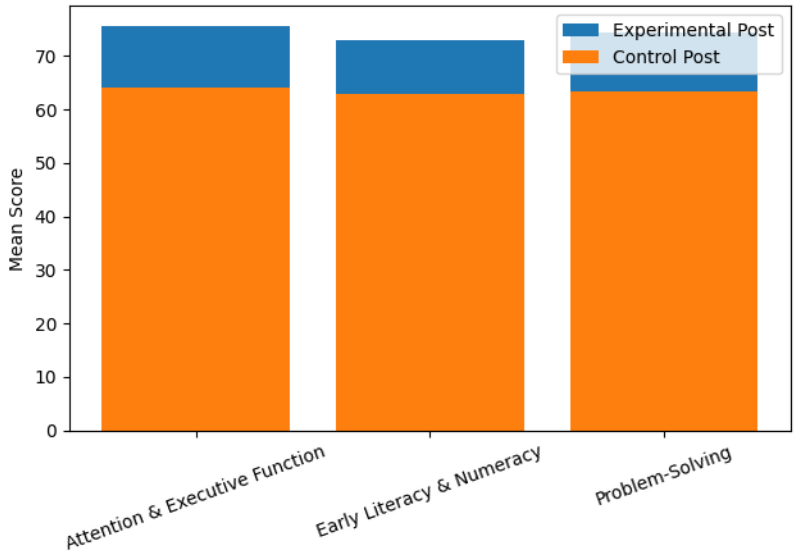

Figure 2. Post-Test Cognitive Development Scores by Group

Figure 2 provides a visual comparison of post-test cognitive development scores between the experimental and control groups. Children engaged in digital play activities regularly surpassed their classmates in the control group across all cognitive categories. The most significant disparities were noted in attention and executive functioning, succeeded by problem-solving and foundational literacy and numeracy skills. This visual pattern corroborates the statistical findings, emphasizing the cumulative advantages of interactive instructional tools for cognitive engagement and learning. The distinct delineation between groups reinforces the assertion that digitally mediated play, when pedagogically organized, can function as a potent cognitive enhancement instrument in early childhood education.

c. Effects of Digital Play on Socio-Emotional Development

The results demonstrated substantial favorable impacts of digital play on the socio-emotional development of preschoolers in the experimental group. Emotional regulation scores shown a statistically significant enhancement from pre-test to post-test ($p < .05$), indicating an increased capacity to manage emotions and maintain interest during learning activities. The control group exhibited merely negligible improvements. Distinct disparities in social interaction and cooperation were noted, with children in the experimental group demonstrating elevated levels of turn-taking, collaborative problem-solving, and constructive peer communication relative to their peers.

Moreover, outcomes pertaining to empathy and peer interactions exhibited considerable enhancement among youngsters engaged in interactive digital play. Ratings from teachers and observers suggested improved perspective-taking, heightened attentiveness to peers' emotions, and increased positive peer attachments. Statistical analyses between groups indicated substantial post-test differences favoring the experimental group across all socio-emotional metrics ($p < .05$). Effect size estimates varied from moderate to large (Cohen's $d = 0.50–0.70$), signifying that the observed improvements were both statistically significant and educationally substantial. These findings highlight the capacity of effectively facilitated digital play to enhance comprehensive socio-emotional growth in early childhood environments, as shown in Table 3.

Table 3. Pre- and Post-Test Socio-Emotional Development Scores and Effect Sizes

Socio-Emotional Domain	Experimental (Pre)	Experimental (Post)	Control (Pre)	Control (Post)	Effect Size (Cohen's d)
Emotional Regulation	58.3	72.4	58.0	61.5	0.66
Social Interaction & Cooperation	59.1	74.1	58.7	62.3	0.70
Empathy & Peer Relationships	57.8	73.6	57.5	61.9	0.63

Table 3 displays comparative pre- and post-test outcomes for socio-emotional development across three principal domains. The children in the experimental group shown significant enhancements in emotional control, social interaction and cooperation, and empathy towards peers after engaging in digital play activities. Conversely, the control group exhibited just marginal improvements. Effect size estimations varied from moderate to large (Cohen's $d = 0.63–0.70$), signifying that the observed changes were educationally significant. The findings indicate that interactive digital play, facilitated by teacher mediation, can enhance socio-emotional abilities crucial for early childhood development and constructive classroom participation, as shown in Figure 3.

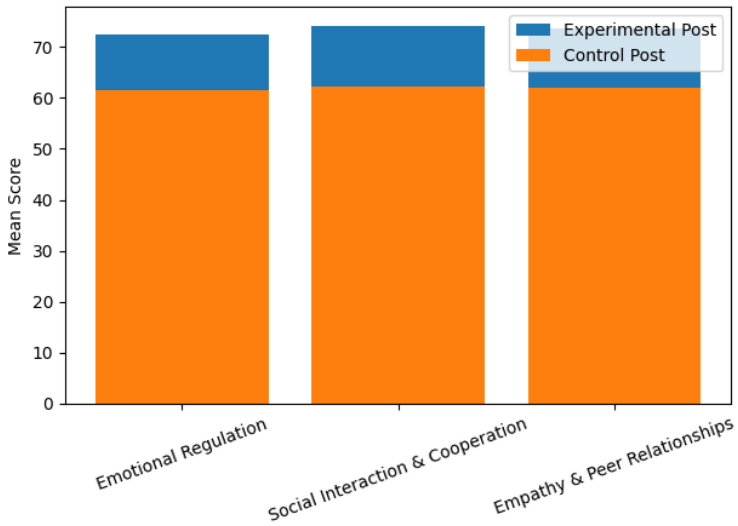

Figure 3. Post-Test Socio-Emotional Development Scores by Group

Figure 3 depicts the post-test socio-emotional development scores for both the experimental and control groups. In all assessed domains, children engaged in digital play consistently attained superior scores compared to those in conventional learning environments. The most significant group disparities were noted in social interaction and cooperation, succeeded by emotional regulation and empathy. This graphic representation substantiates the data findings by distinctly illustrating the enhanced socio-emotional worth of digitally mediated play activities. The figure illustrates how organized digital play can foster beneficial peer interaction and emotional development when linked with early childhood educational ideas.

d. Classroom Observation Findings

Classroom observations identified specific patterns of children's participation during digital play sessions. The children in the experimental group exhibited elevated levels of sustained attention, curiosity, and task perseverance, especially while engaging with game-based and storytelling applications that offered immediate feedback and adaptive challenges. Digital play activities frequently prompted exploratory behaviors, including trial-and-error tactics and self-directed problem solving, signifying active cognitive engagement rather than passive screen usage.

Instances of collaborative behaviors were often noted during small-group digital play. Children participated in turn-taking, collective decision-making, and verbal negotiation during task completion, indicating that interactive technologies enhanced social interaction when utilized collectively. Affirmative emotional reactions, such as displays of pleasure, assurance, and peer support, were frequently seen, particularly after the successful completion of tasks. Teacher mediation significantly influenced interaction dynamics. Educators provide support by encouraging contemplation, demonstrating suitable social actions, and facilitating emotional regulation during instances of dissatisfaction. This facilitated connection fostered effective engagement and ensured that digital play was developmentally suitable, socially significant, and consistent with educational goals, as shown in Table 4.

Table 4. Classroom Observation Indicators During Digital Play Activities

Observation Indicator	Experimental Group (Mean)	Control Group (Mean)
Sustained Engagement	4.5	3.1
Collaborative Interaction	4.3	3.0
Positive Emotional Expression	4.6	3.2
Peer Negotiation	4.1	2.9
Teacher Scaffolding	4.7	3.3

Scale: 1 = Very Low, 5 = Very High

Table 4 delineates the outcomes from classroom observations, contrasting behavioral markers between the experimental and control groups. Children participating in digital play had significantly elevated levels of sustained engagement, collaborative interaction, and positive emotional expression. Peer negotiating behaviors, including turn-taking and collaborative decision-making, were more prevalent in the experimental group. Teacher scaffolding was notably more evident during digital play sessions, indicating active adult mediation. Conversely, the control group exhibited diminished frequencies across all indicators. These findings indicate that organized digital play, facilitated by teacher support, enhances cognitive, social, and emotional engagement in early childhood classroom settings, as shown in Figure 4.

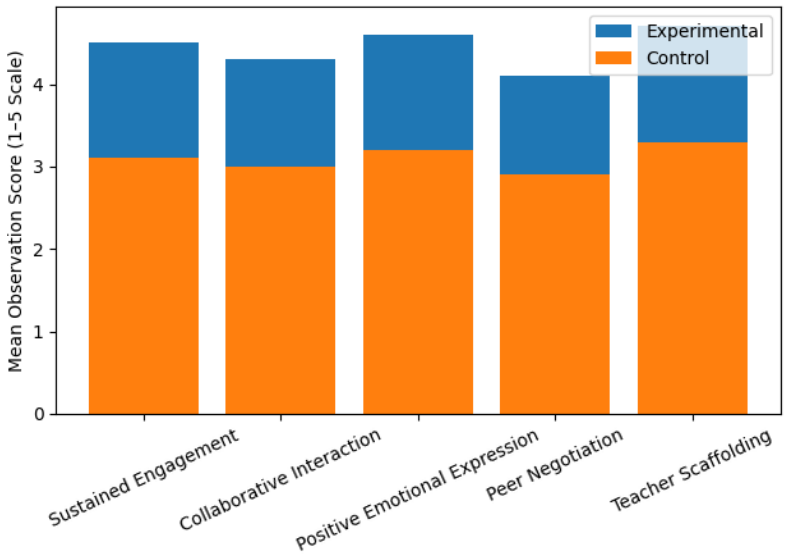

Figure 4. Classroom Observation Indicators During Digital Play

Figure 4 provides a visual comparison of average observation scores for essential engagement and interaction metrics during classroom activities. The experimental group consistently surpassed the control group in all measured aspects, with the most significant disparities reported in teacher scaffolding and positive emotional expression. This image illustrates how carefully designed digitally mediated play settings foster active involvement and significant social connection. The distinct visual contrast underscores qualitative observations that digital gaming can alter classroom dynamics from passive participation to collaborative, emotionally engaged learning experiences. These findings

underscore the essential importance of pedagogical design and teacher facilitation in optimizing the developmental advantages of digital play in early childhood education.

e. Summary of Key Results

This study offers a comprehensive analysis of the impact of digital play on the cognitive and socio-emotional development of preschoolers. Quantitative results indicated that children engaged in interactive digital play activities had markedly superior enhancements in attention and executive functioning, early literacy and numeracy, and problem-solving skills relative to their counterparts in traditional play-based environments. The cognitive improvements were substantiated by moderate to high effect sizes, signifying significant developmental influence.

Concurrently, socio-emotional outcomes demonstrated significant improvements in emotional regulation, social interaction, cooperation, and empathy among children in the experimental group. Classroom observation data further validated these findings by emphasizing heightened involvement, collaborative actions, and positive emotional expressions during digital play sessions. Teacher mediation has become a vital element in promoting effective relationships and ensuring developmentally suitable learning experiences. These results closely correspond with the study's research aims, which sought to assess the influence of interactive educational technology on cognitive and socio-emotional domains. The findings affirm that well-structured and pedagogically facilitated digital play can function as an effective and comprehensive learning method in early childhood education, evidenced by consistent advancements across various developmental dimensions, as shown in Table 5.

Table 5. Integrated Summary of Cognitive and Socio-Emotional Outcomes

Outcome Domain	Experimental Gain Score	Control Gain Score	Overall Effect Size (d)
Attention & Executive Function	13.2	2.3	0.68
Early Literacy & Numeracy	12.3	2.5	0.54
Problem-Solving	13.2	2.6	0.61
Emotional Regulation	14.1	3.5	0.66
Social Interaction & Cooperation	15.0	3.6	0.70
Empathy & Peer Relationships	15.8	4.4	0.63

Table 5 provides a comprehensive assessment of essential cognitive and socio-emotional outcomes by juxtaposing gain scores and impact sizes across many categories. Children in the experimental group exhibited significantly greater developmental advancements than those in the control group across all metrics. Significant enhancements were noted in socio-emotional domains, especially in empathy and social collaboration, subsequently followed by cognitive results like attention control and problem-solving. Effect size estimates varied from moderate to big, affirming the instructional relevance of the findings. This comprehensive presentation emphasizes the overall influence of digital play, underscoring the interrelated aspects of cognitive and socio-emotional development in early childhood educational settings.

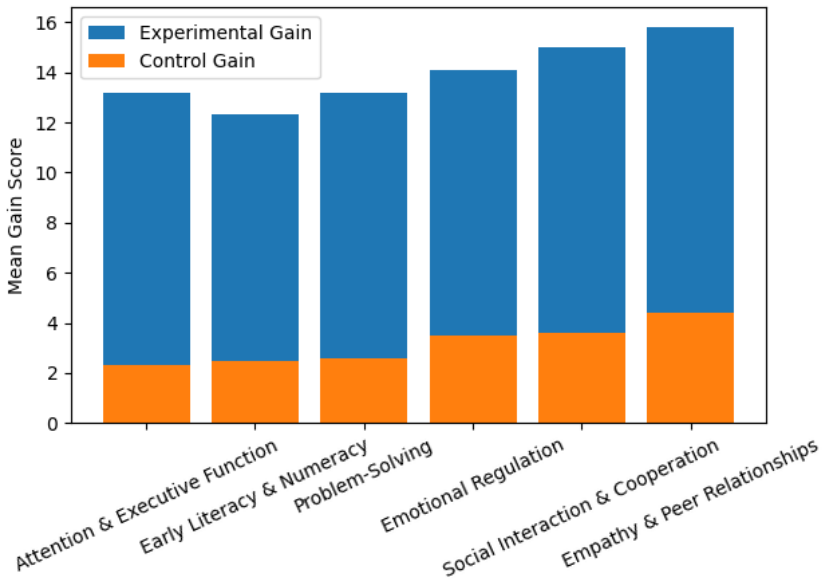

Figure 5. Integrated Gain Scores Across Cognitive and Socio-Emotional Domains

Figure 5 visually synthesizes gain scores across cognitive and socio-emotional categories, sharply contrasting the experimental and control groups. The data demonstrates continuously superior gains for youngsters engaged in interactive digital play, particularly notable in socio-emotional competencies. Cognitive domains exhibit significant benefits, suggesting that digital play enhances both academic and emotional aspects of development. This integrated graphic offers a concise and persuasive summary of the study's principal findings, demonstrating that digital play operates as a multifaceted educational strategy rather than a singular outcome intervention. The chart reinforces the correlation between study aims and empirical outcomes.

3.2 Discussion

a. Interpretation of Cognitive Development Findings

This study's findings demonstrate that digitally mediated play significantly impacts preschoolers' cognitive development, especially in attention regulation, problem-solving, and foundational academic skills. Interactive digital play environments seemed to prolong children's attention by providing explicit objectives, prompt feedback, and tailored challenges. These elements facilitated executive functioning by prompting youngsters to strategize actions, assess progress, and modify approaches when encountering challenges. Enhancements in problem-solving abilities were particularly noticeable in tasks necessitating trial-and-error exploration and logical reasoning, indicating that digital gaming fostered active cognitive involvement rather than passive consumption.

The findings corroborate prior research on digital play and early learning, indicating that well-designed educational tools positively influence early literacy and numeracy development (Norman, 2023; Roberts-Tyler et al., 2023). This study enhances current literature by demonstrating that cognitive improvements are most significant when digital technologies are integrated into play-based learning environments and facilitated by instructor intervention. Interactivity and feedback were pivotal to these outcomes, since responsive digital environments allowed youngsters to obtain rapid reinforcement, rectify

errors, and sustain motivation. These findings highlight the significance of purposefully designed digital play in developing essential cognitive skills in early childhood education.

b. Interpretation of Socio-Emotional Development Findings

The socio-emotional findings suggest that well-designed and mediated digital play can significantly enhance preschoolers' emotional control and social engagement. Children in the experimental group had enhanced ability to regulate frustration, maintain good emotions, and rebound from difficulties during learning tasks. The findings indicate that interactive digital settings, especially those with incremental challenge and explicit feedback, might provide emotionally supportive contexts that facilitate children's self-regulation in developmentally suitable manners.

Significantly, improved social interaction and cooperation were intricately linked to collaborative digital play styles. Small-group activities promoted turn-taking, collaborative decision-making, and verbal negotiation, enhancing peer-oriented social competences (Kalmar et al., 2022; Laakso et al., 2021; Sjöberg & Brooks, 2022). These results highlight the essential function of teacher mediation, as educators facilitated relationships, demonstrated prosocial behaviors, and supported emotional reactions during instances of conflict or challenge. In the absence of such mediation, the socio-emotional advantages of digital play may be reduced.

These findings are consistent with socio-constructivist and play-based learning theories, which highlight learning as a socially mediated process rooted in interaction and collaborative meaning-making. Digital play served not as a replacement for social play, but as an augmentation of it establishing novel arenas for cooperation, emotional articulation, and structured engagement. Consequently, when integrated into play-based pedagogies, digital devices can enhance the social and emotional foundations crucial for early learning and development (Demirdis, 2024; John & Bates, 2024).

c. Digital Play as a Curriculum-Supported Pedagogical Tool

This study's findings emphasize the educational potential of digital play when purposefully incorporated into preschool curricula. Digital play was most beneficial when integrated with curricular objectives pertaining to cognitive and socio-emotional development, rather than being treated as a standalone activity. This integration enables interactive technologies to enhance current play-based methods by broadening chances for exploration, problem-solving, and social connection. Consequently, digital play can function as a curriculum-enhancing instrument that augments learning experiences while preserving fundamental early childhood educational concepts.

It is crucial to keep a balanced methodology between digital and traditional play-based learning. Although digital play provides distinct advantages like adaptive feedback and multimodal interaction, conventional physical and symbolic play is essential for motor development and imaginative expression (Dahlström, 2022; Tang et al., 2024). The results indicate that a deliberate combination of digital and non-digital play fosters comprehensive development by utilizing the advantages of both modalities. Educators provide a pivotal function in facilitating technology-enhanced play. Effective teacher mediation entails the selection of developmentally suitable digital tools, supporting children's activities, and facilitating reflection to align digital experiences with educational objectives (Chiner et al., 2025; Farrell et al., 2024). Teachers actively facilitate to ensure that digital play is meaningful, socially engaged, and pedagogically integrated within the preschool curriculum.

d. Theoretical Implications

This study enhances early childhood curriculum theory by providing a refined comprehension of the systematic integration of digital play into play-based curricular frameworks, while preserving essential developmental principles. The findings endorse a curriculum perspective that regards digital play not as an adjunct, but as a pedagogical approach that can be intentionally aligned with learning objectives, developmental phases, and social interaction patterns in early childhood education (Clark et al., 2023; Lähdesmäki et al., 2024). This viewpoint enhances curriculum theory by broadening conventional concepts of play to encompass digitally mediated experiences that are both child-centered and developmentally suitable.

The research provides significant insights into the correlation between digital play and comprehensive child development. The findings, by illustrating simultaneous advancements in cognitive and socio-emotional domains, contest binary perspectives that distinguish academic learning from emotional and social development. Digital play serves as an integrative learning environment wherein cognition, emotion, and interaction are mutually reinforcing processes (Lehrl et al., 2021). The findings have significant implications for developmental and learning theories within early childhood education environments. They bolster socio-constructivist principles that learning arises through mediated contact and guided involvement, while also broadening play-based learning theories to include technologically enhanced contexts (Zhou, 2025). This theoretical integration advocates for a modern, inclusive framework of early childhood education in the digital age.

e. Practical Implications

This study's findings present multiple practical implications for early childhood educators. Educators are urged to include digital play as an organized element of instructional practice instead of treating it as an ancillary or leisure activity. Choosing developmentally suitable, interactive digital tools and incorporating them into everyday learning practices can improve children's cognitive engagement and socio-emotional growth. The utilization of collaborative digital play models that foster peer engagement, communication, and emotional regulation is equally significant.

The findings emphasize the necessity for curriculum designers and legislators to explicitly incorporate digital play into early childhood curricular frameworks. Explicit curricular standards must prioritize balanced integration, guaranteeing that digital play enhances rather than supplants traditional play-based learning. Policies must facilitate fair access to superior educational technology and establish criteria for age-appropriate digital material in preschool environments. The research underscores the significance of professional advancement in digital pedagogy. Educators necessitate continuous professional development to proficiently facilitate technology-enhanced play, encompassing techniques for scaffolding learning, regulating classroom interactions, and connecting digital activities with educational objectives. Focused professional development can enable educators to utilize digital play both safely and creatively, so improving the quality of early childhood education in progressively digital learning contexts.

4. CONCLUSION

This study investigated the influence of digital play through interactive educational technology on preschoolers' cognitive and socio-emotional development in play-based early childhood learning environments. This research aimed to furnish empirical evidence on the extent to which digitally mediated play can facilitate holistic development when incorporated into the preschool curriculum, amidst ongoing discussions about the role of digital technologies in early childhood education. The results indicated that digital play positively and significantly impacted children's learning outcomes. Quantitative findings indicated substantial enhancements in critical cognitive areas, such as attention and executive functioning, early reading and numeracy, and problem-solving skills among children engaged in the digital play intervention. Concurrently, socio-emotional outcomes demonstrated significant improvements in emotional control, social interaction, cooperation, and empathy. The results were corroborated by classroom observation data, which indicated elevated engagement, collaborative behaviors, positive emotional responses, and effective teacher mediation during digital play sessions. The findings collectively affirm that digital play, when pedagogically organized and facilitated by educators, serves as an integrated learning method that promotes cognitive and socio-emotional growth.

Notwithstanding these contributions, this work also paves the way for future research opportunities. Longitudinal studies are essential to investigate the enduring impacts of digital activity on developmental trajectories throughout time. Subsequent study may investigate variances in digital play design, degrees of teacher mediation, and cultural or contextual disparities across early childhood environments. Such investigations would enhance comprehension of how digital play might be effectively integrated into early childhood curricula to foster development in an increasingly digital environment.
